Questions

1.What is ML?
Machine learning is teaching computers to learn patterns from data and make predictions or decisions, instead of programming every rule by hand.

2. What is MLflow?
An open-source tool that helps you track experiments, save models, and manage the whole ML lifecycle in one place.
What is an MLflow run?
One execution of your training code. Each run records its parameters, metrics, and output files (like the model), so you can compare runs later.

3. What is a parameter?
A setting you choose before training, like learning rate, number of trees, or batch size. In MLflow, you log these as inputs to a run.

4. What is a metric?
A number that tells you how well the model did, like accuracy, F1-score, or loss. In MLflow, you log these as outputs of a run.

5. What is MLOps?
DevOps practices applied to ML. It covers building, deploying, monitoring, and retraining models so they work reliably in production.

6. Why use Docker?
It packages your code, libraries, and environment into a container, so it runs the same everywhere: "works on my machine" stops being a problem.

7. What is CI/CD?
Continuous Integration/Continuous Delivery. CI automatically tests and merges code changes; CD automatically deploys them. Together they make releases faster and safer.
